Introduction

The International Waterbird Census (IWC) is one of the largest global biodiversity monitoring scheme with more than 140 countries worldwide participating. The African-Eurasian Waterbird Census covers the 118 countries in the African-Eurasian flyway of which over 90 contribute to the scheme. The aim of the IWC is to support the conservation of waterbird species by estimating their population size, assessing the changes in their numbers and to identify key sites for them.

This report contains the results of the regular triennial trend analyses based on IWC counts. These analyses, together with other additional data, provide input into the AEWA Conservation Status Report (Figure 1), which forms the basis of adjusting Table 1 of the AEWA Action Plan that determines the management regime Contracting Parties to AEWA shall apply.

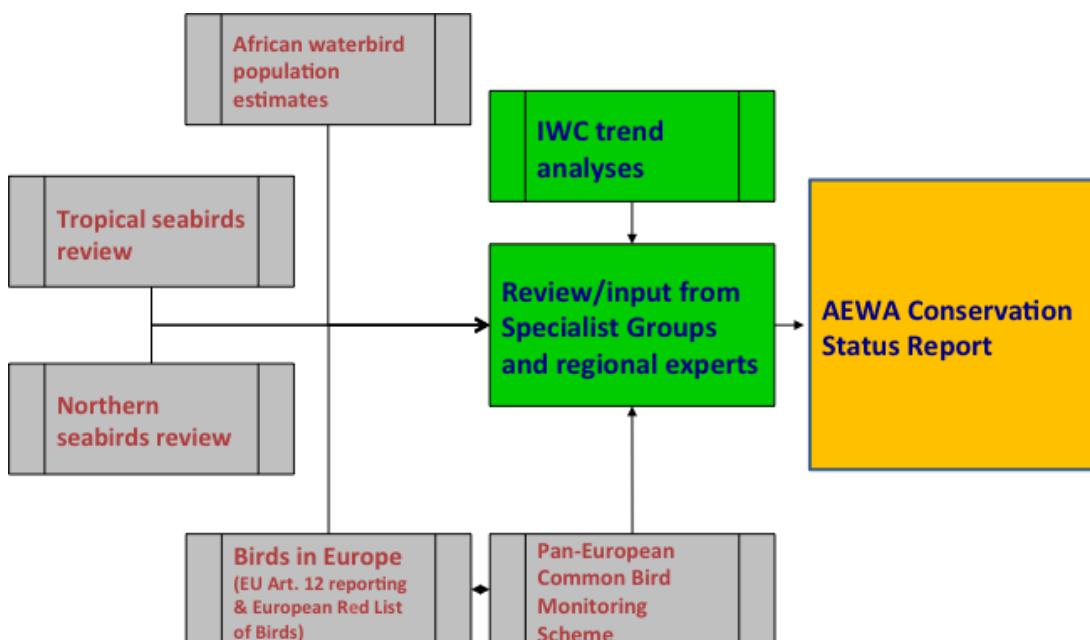

Figure 1. Inputs into the AEWA Conservation Status Report

It is important to emphasise that trend analyses based on IWC count data are only one of the many inputs considered when estimating the size of waterbird populations and the results are compared with other sources of information. Therefore, readers are advised to use this document only as a **background document** and should refer to the population size and trend estimates available through the Waterbird Population Estimates portal (wpe.wetlands.org) instead of using the raw trend assessments published here.

Materials and methods

The International Waterbird Scheme is a synchronised annual counting scheme implemented every January across the flyway and also in July in Africa. The scheme is coordinated by national organisations that together form the African-Eurasian Waterbird Monitoring Partnership. The scheme is most suitable for monitoring waterbird populations that congregate on inland wetlands or near-shore coastal areas during the time of counts and populations that are distinct from other conspecific population during this period. The scheme is less suitable to monitor populations that (partly) occur on offshore waters or farmland or rangeland habitats or which are dispersed during the time of counts. Good coverage of suitable habitats is essential to obtain reliable population size and trend estimates and the reliability of the results diminish where this is not the case as demonstrated in the trend graphs.

For this analysis we have extracted 1.8 million records from the International Waterbird Census database from the period of 1988 and 2012 for the species listed in Annex 2 of the African-Eurasian Waterbird Agreement and for which we considered the IWC data suitable to assess their status considering also the availability of other data sources (see TRIM column in Table 1).

Each site was allocated to the relevant waterbird populations using GIS overlay of the site locations with polygons of the population flyways, which are also available on the Critical Site Network Tool (<http://dev.unep-wcmc.org/csn/default.html#state=home>), and applying a set of exclusion rules in the overlap areas (see section on trend graphs).

Following this, the latest 5-year annual count totals was compared to the minimum of the population size estimate from the 5th edition of Waterbird Population Estimates and data were prepared for trend analysis only if the 5-year mean of the annual count total for the population has exceeded 10% of the minimum population estimate (see % column in Table 1). In some cases, when no alternative source of population trend estimates were available, exceptions were made from this rule.

For the populations that were retained for trend analysis, sites with less than two positive counts were excluded to avoid accounting for missing counts at sites with irregular occurrence of the population. If the number of sites exceeded 4,000 (the limit of the number of sites the TRIM software able to handle), we selected sites holding over 1% of the 1% threshold. This usually resulted in a negligible (less than 5%) reduction in the totals. If the number of sites remained over the 4,000 limit after the application of this rule (*Fulica atra atra*, NW Europe (non-bre) and *Anas platyrhynchos platyrhynchos*, NW Europe (non-bre)), we increased the number of visits with positive counts from 2 to 3 and so on until we got less than 4,000 sites.

As zero counts are conventionally not recorded, we applied a series of tests to decide whether the absence of the species in a count represents 0 or the species was likely to be present, but not counted, in which case we imputed for missing counts. We applied the procedure described in van Roomen et al. (2011).

Trend analyses were carried out using TRIM 3.54 through BirdSTATS v 2.03. We used time-effect models with overdispersion and temporal autocorrelation settings. After the first run, the ratio of real counts to the imputed total were assessed and the analysis was rerun for the period when majority of the years when real counts were more than 30% of the total.

According to the AEWA Resolution 5.7¹, "A population in 'significant long-term decline' is one where the best available data, information or assessments indicate that it has declined by at least 25% in numbers or range over a period of 25 years or 7.5 generations, whichever is the longer or when similar decline can be predicted based on at least 10 years of the most recent data". The implication of this definition is that the trend classification produced by TRIM is incorrect in this context and the slope value should be compared to a value that is calculated based on the generation length (BirdLife International, 2014) using the following function:

$$D = e^{\frac{\ln(1-0.25)}{7.5*GL-1}}$$

Where:

D: the threshold for multiplicative annual rate of change that would qualify as significant long-term decline
GL: generation length in years

Classification of the trends otherwise followed the scheme described in Pannekoek and van Strien (2005). However, trend assessments presented in Table 2 were critically compared to other sources of information on population trend and bias in data collection was also considered when assessing the trend. These additional data and the final trend assessment can be found in the relevant population accounts under the CSR 6 draft² publication on the Waterbird Population Estimates portal³.

<i>Podiceps cristatus infuscatus</i> , Eastern Africa (Ethiopia to N Zambia)	+	?	9	+	On average, 201 individuals counted annually

⁴ Population selected for TRIM analysis based on when the population can be separated from other populations, its distribution pattern and habitat use that determines the utility of the core IWC counts to estimate population size and trend.

⁵ Five year count total in proportion of the minimum population estimate. ? indicate populations where the minimum population estimate is 1.

⁶ Number of years the proportion of real counts was less than 30%, i.e. more than 70% of the totals were imputed.

⁷ Indicates whether a trend analysis for the population is included in this report.
